## TEST SETUP:

The telephones were measured per TIA-470B, 1997. The drive level was -10 dBV (open circuit) from a 900 ohm source. The receive frequency response was measured using an IEC-318 ear coupler and a 1/2 inch pressure microphone (B&K 4192). All test equipment is manufactured and calibrated by Bruel and Kjaer.

**Figure 15**  
**Test Circuit**

## ROLR and SPL:

One source of confusion is the difference between Sound Pressure Level (SPL) and Receive Objective Loudness Rating (ROLR) in determining how loud a telephone is.

ROLR is calculated according to IEEE-661, from the frequency response data between 300 to 3300 Hz. The response is the ratio of the sound pressure, in Pascals, to the voltage measured across a 900 ohm calibration resistor in place of the telephone. Since the voltage is divided in half the voltage used in the calculation is 6 dB less than the open circuit voltage. The actual voltage across the telephone under test will be different depending on its impedance.

**ROLR is calculated using losses therefore the more positive the ROLR the quieter it is.** For example 40 is louder than 50.

If the telephone is linear the drive level does not effect the receive loudness. For example, a drive level of -10 dBV open circuit will produce the same ROLR as a -20 or -30 dBV level since a reduction in voltage causes an equal drop in sound pressure and therefore the ratio of sound pressure to input voltage remains constant.

SPL, however, is dependent on the drive level. When driven with a -10 dBV open circuit voltage, as shown in **Figure 15** the nominal sound pressure at 1 kHz is 94 dB SPL measured in the artificial ear. If the drive level is changed the SPL changes therefore it is meaningless to state a SPL level without the corresponding drive level. The long term average SPL on local calls is around 84 dB SPL (I didn't confirm this).

A 1 dB louder ROLR will result in a 1 dB increased SPL unless the shape of the frequency response curve changes. **Figure 5** illustrates a scenario where the frequency response curve does change. In this case the volume control range is 10 dB using ROLR (43.5 - 33.5) but is 14.9 dB using SPL as an indicator (111.8 dB - 96.9 dB).

### Section 1193.43 Output, display, and control functions [1193.37 in the NPRM]

#### Paragraph (e) Availability of auditory information for people who are hard of hearing

Comment. The majority of comments from persons who are hard of hearing reported having trouble using public pay telephones because of inadequate receiver amplification levels. These commenters supported the proposed provision that products be equipped with volume control that provides an adjustable amplification ranging from 18-25 dB of gain. However, TIA and several manufacturers cited the National Technology Transfer and Advancement Act of 1996, which requires the Federal government to make use of technical specifications and practices established by private, voluntary standards-setting bodies wherever possible. Furthermore, TIA claimed that the higher range will result in signals encroaching on the acoustic shock limits of telephone receiver output. TIA recommended that this section be revised to reflect a general performance standard, similar to the recommendation in the TAAC report. Some comments pointed out that there was no baseline signal against which the gain is to be measured. That is, for a weak signal even 18-25 dB of gain may be ineffective, while for a strong signal, the present ADAAG and FCC requirement of 12-18 dB may be sufficient. Also, industry commenters said that increasing gain may not be the only, or even the best way to provide better access since amplifying a noisy signal also amplifies the noise.

Response. Information submitted by SHHH indicates that the proposed gain of 25 dB is not a problem for current telephone technology. The information was based on testing conducted by two independent laboratories (Harry Teder Ph.D., Consulting in Hearing Technology and Harry Levitt, Ph.D., Director, Rehabilitation Engineering and Research Center on Hearing Enhancement and Assistive Devices, Lexington Center). High gain phones without special circuitry currently on the market were tested which put out 90 dB and 105 dB at maximum volume setting. This is a 20 dB gain over the standard 85 dB. The sound was clear with no distortion. SHHH said that this shows that a 90 dB and 105 dB clean speech level is achieved with phones commercially available with no worse distortion levels than on public phones at normal levels. With special circuits and transducers, telephones could generate even higher amplification levels, above 25 dB, without distortion.

The current FCC standard for 12-18 dB of gain was adopted from ADAAG which requires certain public pay telephones to provide a gain of 12-18 dB. However, this provision is frequently incorrectly applied so that the gain only falls somewhere within this range but does not reach the 18 dB level. In fact, the requirement is to provide gain for the entire range of 12-18 dB.

The Board is currently reviewing all of its ADAAG provisions and will be issuing a NPRM in 1998 which will propose a new ADAAG. The changes to ADAAG will be based on recommendations of the Board's ADAAG Review Advisory Committee. That Committee recommended increasing the gain for public pay telephones from 12-18 dB to 12-20 dB. Recently, the ANSI A117.1 Committee released its 1997 "Accessible and Usable Buildings and Facilities" standard. This voluntary standard-setting body issues accessibility standards used by the nations model building codes. The ANSI standard requires certain public pay telephones to provide 12 dB of gain minimum and up to 20 dB

maximum and that an automatic reset be provided. The 1997 ANSI A117.1 document and the Board's new ADAAG are being harmonized to minimize differences between the two documents.

Therefore, in accordance with the National Technology Transfer and Advancement Act, the final rule has been changed to adopt the provision as currently specified in the private, voluntary ANSI standard, with wording to clarify its meaning. For example, the ANSI provision was written under the assumption of an incremental, stepped volume control. If a volume adjustment is provided that allows a user to set the level anywhere from 0 to the upper requirement of 20 dB, there is no need to specify a lower limit. If a stepped volume control is provided, one of the intermediate levels must provide 12 dB of gain. Although the final rule does not provide the higher 25 dB level as proposed in the NPRM, the Board intends to highlight this provision for evaluation in its market monitoring report. If the Board's market monitoring report shows that persons with hearing impairments continue to report having trouble using telephones because the level of amplification is not high enough, the Board will re-evaluate this provision.

Recently, the FCC issued an order 5 postponing until January 1, 2000, the date by which all telephones covered by Part 68 must be equipped with a volume control. This order was issued as a response to a request for reconsideration asking that the requirement only be applied to new equipment. That request was denied but the time for compliance was extended to take into account its application to telephones already registered under Part 68.

The guidelines only apply to telecommunications equipment and customer premises equipment designed, developed and fabricated after [insert date 30 days after publication]. Therefore, the guideline provision does not conflict with the FCC order. New telephones will be covered by these guidelines and existing telephones will have until January 1, 2000, to comply with the FCC Order.

### NOTICE OF PROPOSED RULEMAKING

Adopted: April 2, 1998

Released: April 20, 1998

**Comment Date: June 30, 1998**

**Reply Comment Date: August 14, 1998**

By the Commission: Commissioners Furchgott-Roth, Powell and Tristani issuing separate statements.

**.Sec. 1193.43 Output, display, and control functions.**

All information necessary to operate and use the product, including but not limited to, text, static or dynamic images, icons, labels, sounds, or incidental operating cues, shall comply with each of the following, assessed independently:

(a) AVAILABILITY OF VISUAL INFORMATION. Provide visual information through at least one mode in auditory form.

(b) AVAILABILITY OF VISUAL INFORMATION FOR LOW VISION USERS. Provide visual information through at least one mode to users with visual acuity between 20/70 and 20/200 without relying on audio.

(c) ACCESS TO MOVING TEXT. Provide moving text in at least one static presentation mode at the option of the user.

(d) AVAILABILITY OF AUDITORY INFORMATION. Provide auditory information through at least one mode in visual form and, where appropriate, in tactile form.

(e) AVAILABILITY OF AUDITORY INFORMATION FOR PEOPLE WHO ARE HARD OF HEARING. Provide audio or acoustic information, including any auditory feedback tones that are important for the use of the product, through at least one mode in enhanced auditory fashion (i.e., increased amplification, increased signal-to-noise ratio, or combination). For transmitted voice signals, provide a gain adjustable up to a minimum of 20 dB. For incremental volume control, provide at least one intermediate step of 12 dB of gain.

(f) PREVENTION OF VISUALLY-INDUCED SEIZURES. Visual displays and indicators shall minimize visual flicker that might induce seizures in people with photosensitive epilepsy.

(g) AVAILABILITY OF AUDIO CUTOFF. Where a product delivers audio output through an external speaker, provide an industry standard connector for headphones or personal listening devices (e.g., phone-like handset or earcup) which cuts off the speaker(s) when used.

(h) NON-INTERFERENCE WITH HEARING TECHNOLOGIES. Reduce interference to hearing technologies (including hearing aids, cochlear implants, and assistive listening devices) to the lowest possible level that allows a user to utilize the product.

(i) HEARING AID COUPLING. Where a product delivers output by an audio transducer which is normally held up to the ear, provide a means for effective wireless coupling to hearing aids.

#### **Subpart D — Requirements for Compatibility With Peripheral Devices and Specialized Customer Premises Equipment**

##### **Sec. 1193.51 Compatibility.**

When required by subpart B of this part, telecommunications equipment and customer premises equipment shall be compatible with peripheral devices and specialized customer premises equipment commonly used by individuals with disabilities to achieve accessibility, and shall comply with the following provisions, as applicable:

(a) EXTERNAL ELECTRONIC ACCESS TO ALL INFORMATION AND CONTROL MECHANISMS. Information needed for the operation of products (including output, alerts, icons, on-line help, and documentation) shall be available in a standard electronic text format on a cross-industry standard port and all input to and control of a product shall allow for real time operation by electronic text input into a cross-industry standard external port and in cross-industry standard format. The cross-industry standard port shall not require manipulation of a connector by the user.

(b) CONNECTION POINT FOR EXTERNAL AUDIO PROCESSING DEVICES. Products providing auditory output shall provide the auditory signal at a standard signal level through an industry standard connector.

(c) COMPATIBILITY OF CONTROLS WITH PROSTHETICS. Touchscreen and touch-operated controls shall be operable without requiring body contact or close body proximity.

(d) TTY CONNECTABILITY. Products which provide a function allowing voice communication and which do not themselves provide a TTY functionality shall provide a standard non-acoustic connection point for TTYs. It shall also be possible for the user to easily turn any microphone on and off to allow the user to intermix speech with TTY use.

(e) TTY SIGNAL COMPATIBILITY. Products, including those providing voice communication functionality, shall support use of all cross-manufacturer non-proprietary standard signals used by TTYs.
